

Study Guide

this is a place to start, it is not ALL inclusive

learn the big picture first; then dive into the details; seek understanding not memorization

L17: Blood

1. Define hematology, hemopoiesis, hematocrit, and hemostasis.
2. What are the layers of blood that separate out when blood is centrifuged in a test tube; what formed elements are present and where.
3. Name the “formed elements” and their primary function (giving the general function of white blood cells, not specific functions of each type of white blood cell.)
4. Describe hemostasis. What are the 3 steps? Explain what happens in each step.
5. Differentiate hemostasis & homeostasis; fibrin & plasmin; thrombus & embolus; platelet plug & clot & coagulation
6. What are the principal components of a blood clot? How is hemostasis initiated and terminated?
7. RBCs:
 - a. What is their primary function?
 - b. Where are they produced?
 - c. Why replaced so often? ***no way of repairing themselves as they have no nucleus and few organelles***
 - d. What essential nutrient do they need? ***Fe***
8. Clotting factors: What are they? Where are they located? Where are they produced? What is their function?
9. Name the 2 mechanisms that create fibrin so that coagulation of the platelet plug can occur? How are they different and how are they the same?
